To-Do List

The Shared ASP.NET Platform

Demo - Exploring the Application Life Cycle

Handling Requests with Web Forms

Demo - Touring the Legacy Application

Handling Requests with MVC

Understanding Routing

Demo - Routing and Requests in MVC

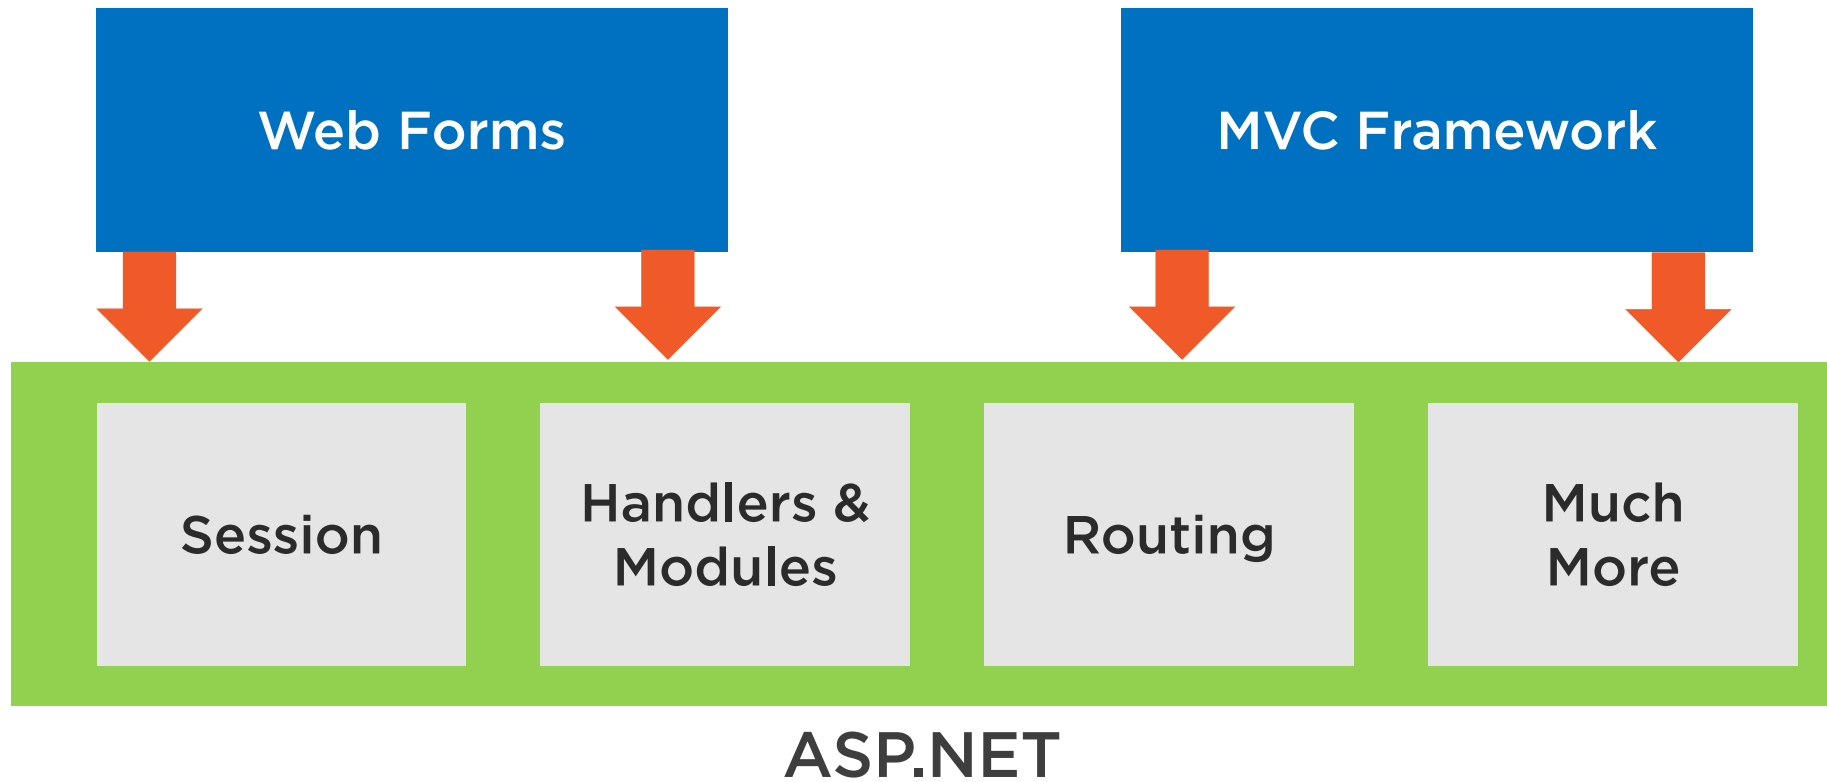

Demo - Building the Controller Structure

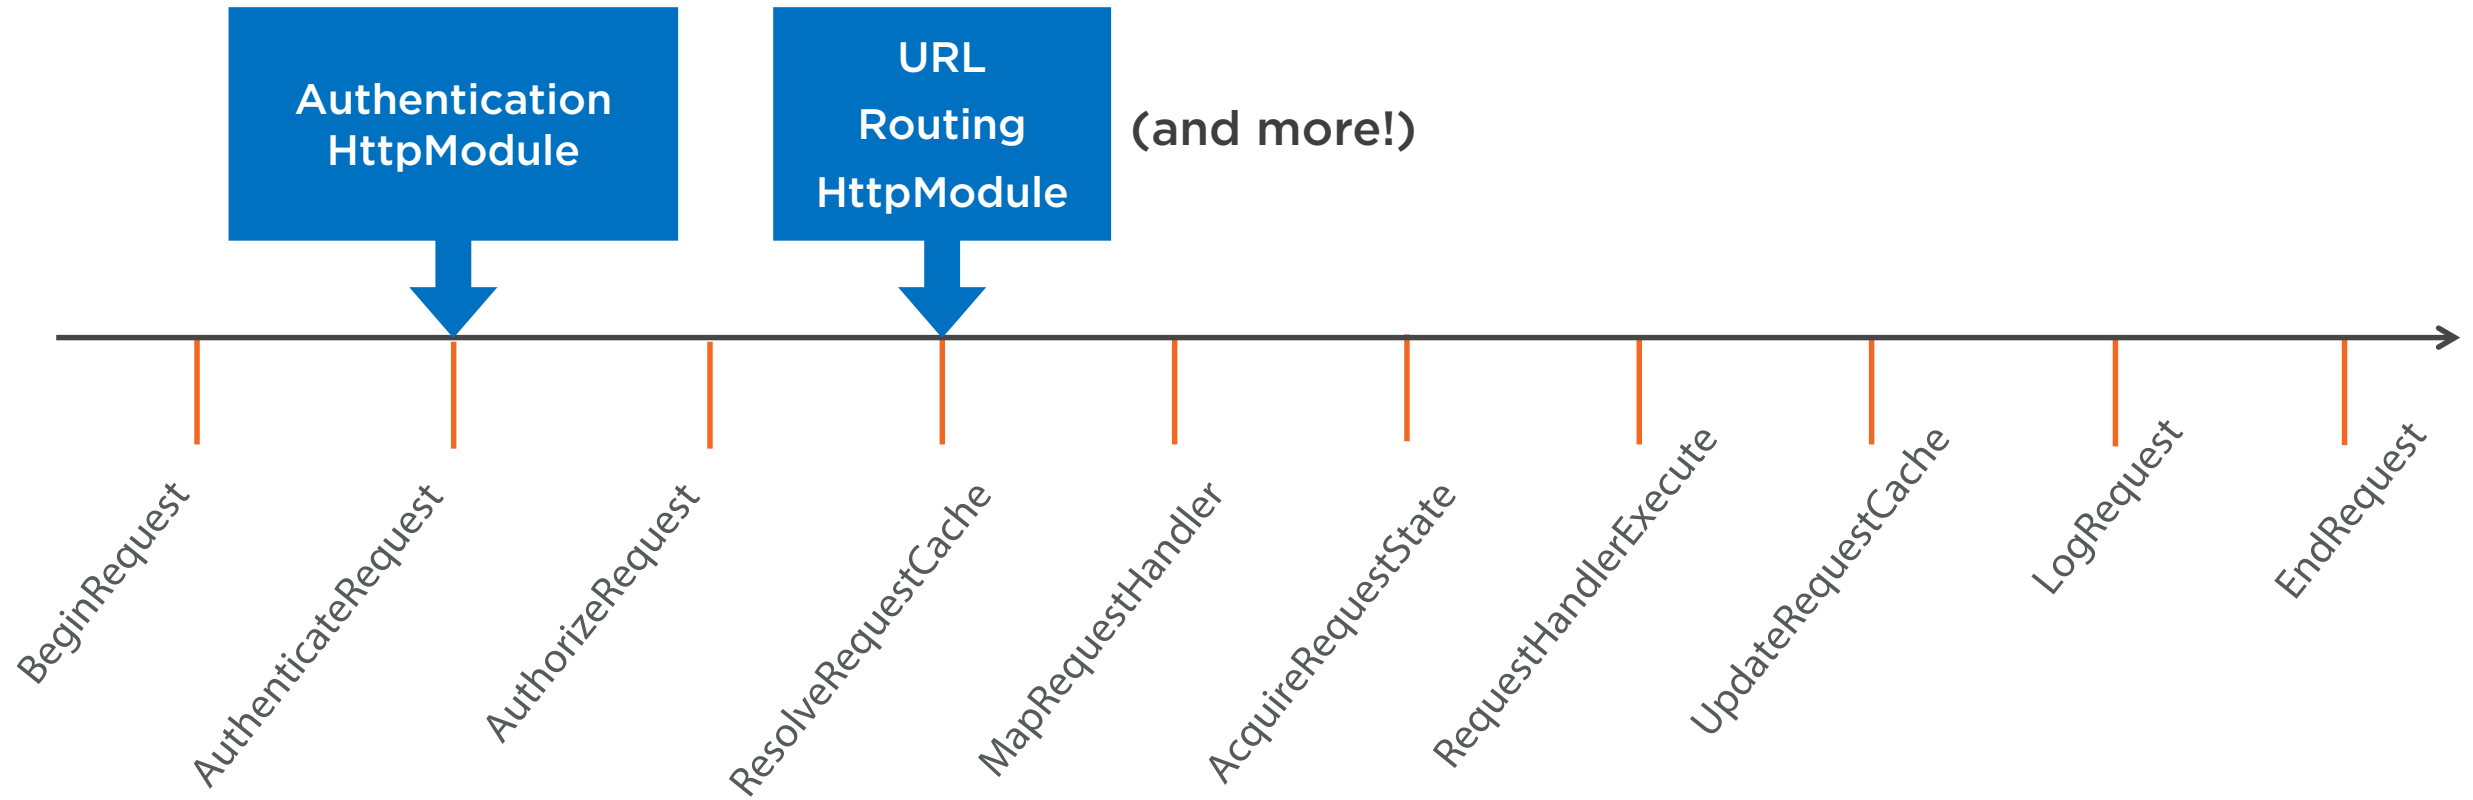

The Shared ASP.NET Platform

A Common Foundation

The ASP.NET Application Life Cycle

* Event names shown represent both pre and post events

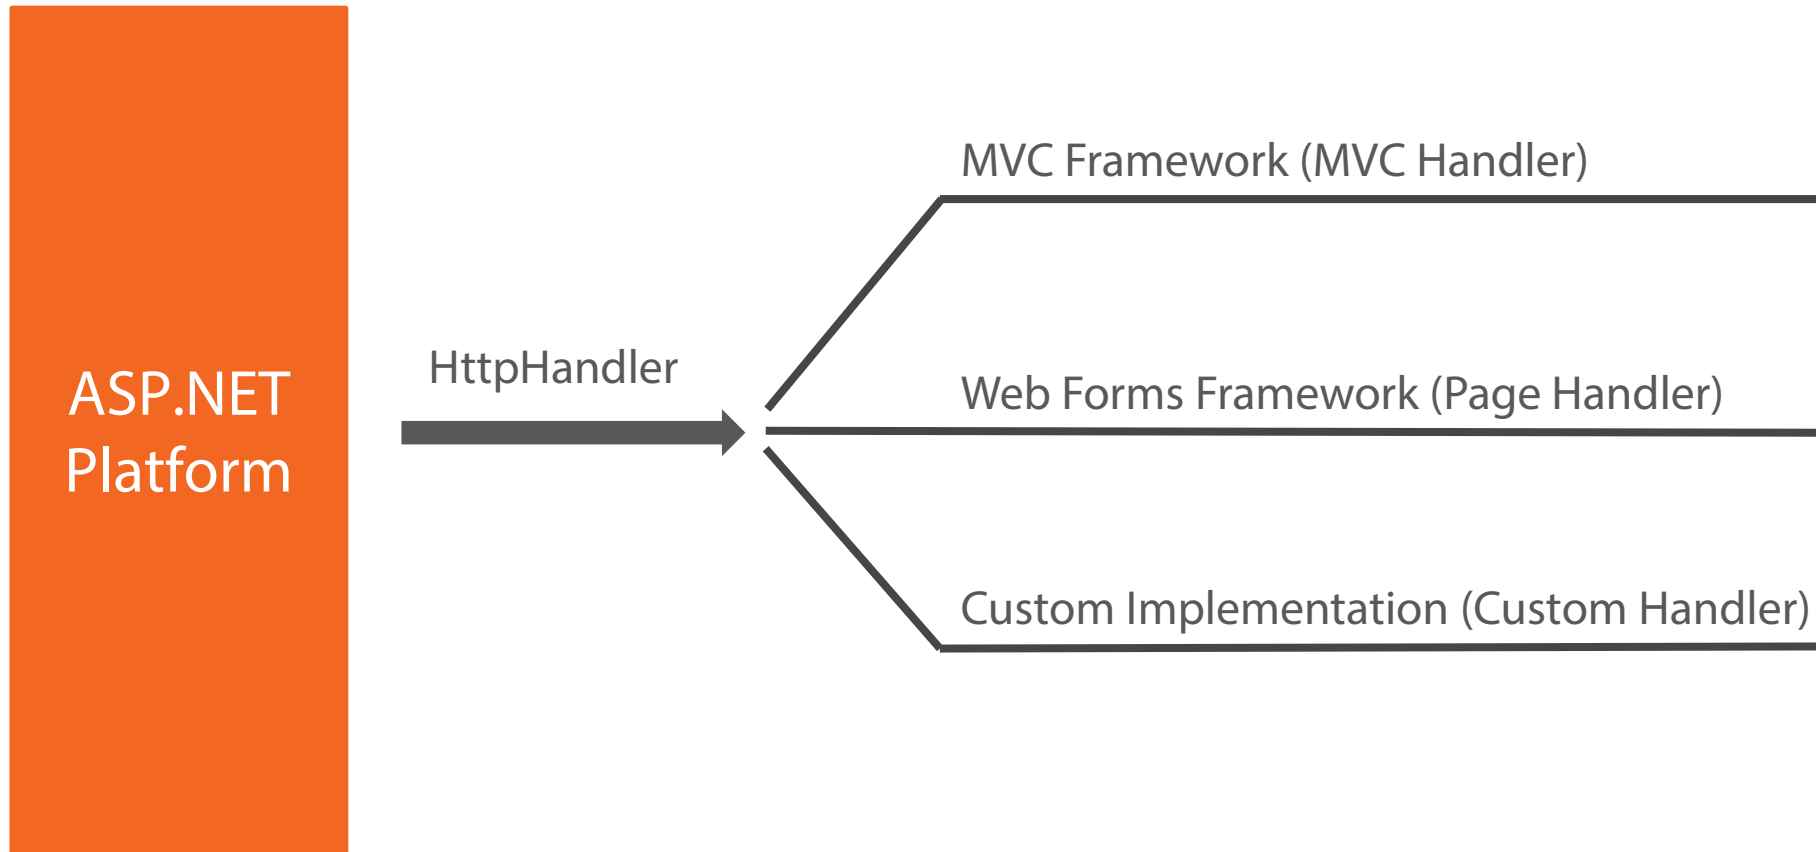

```
public interface IHttpModule {  
    void Dispose();  
    void Init(HttpApplication application);  
}
```

Implementing an IHttpModule
Not an overly common task, but just in case!

One Platform, **Many** Implementations

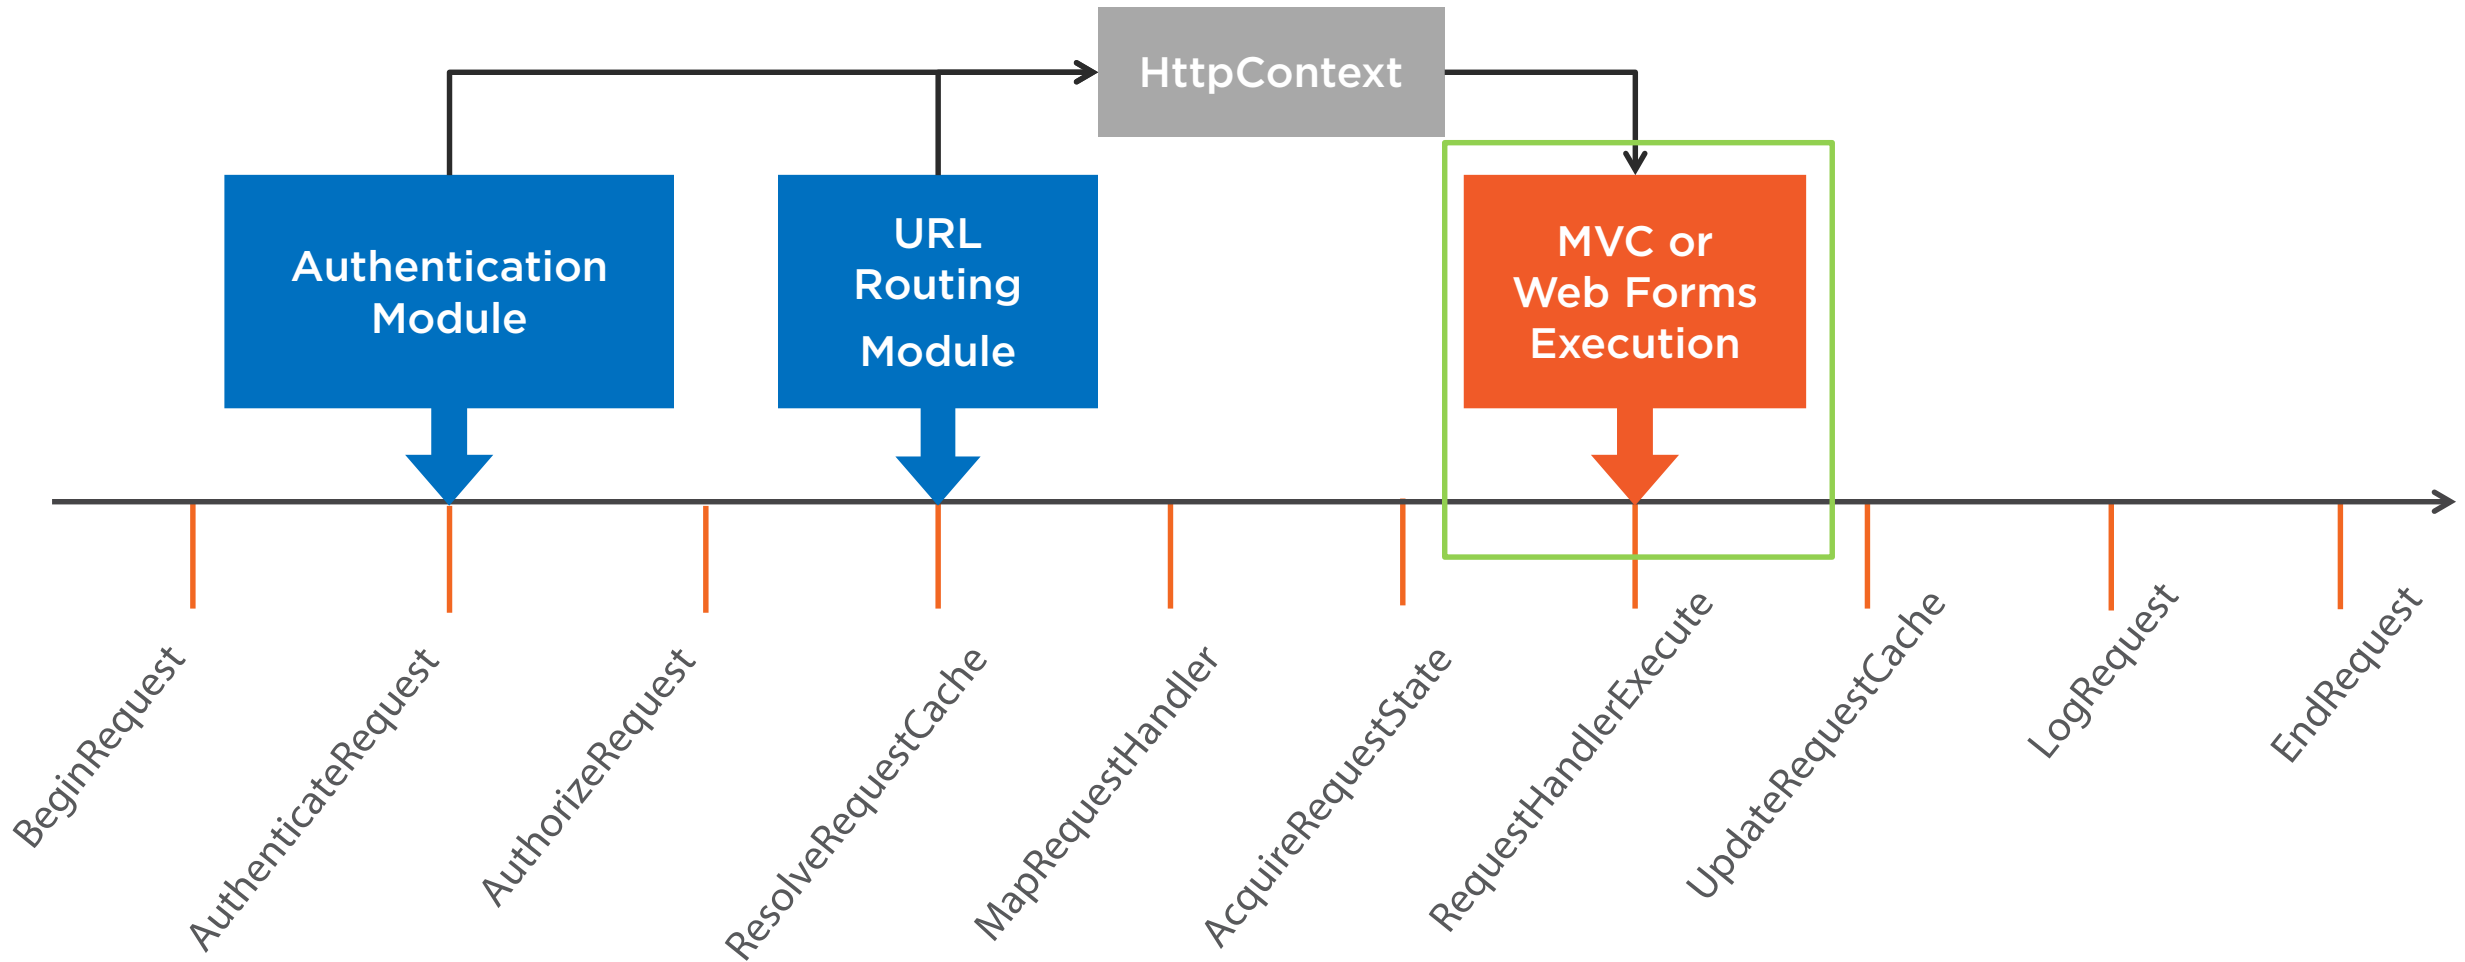

```
public interface IHttpHandler {  
    bool IsReusable();  
    void ProcessRequest(HttpContext context);  
}
```

Implementing an IHttpHandler

Remember, ProcessRequest ultimately generates the response

HttpHandlers and the Application Life Cycle

* Event names shown represent both pre and post events

Summarizing Modules and Handlers

HttpModules

Hook into Application Level Events to provide supporting features

HttpHandlers

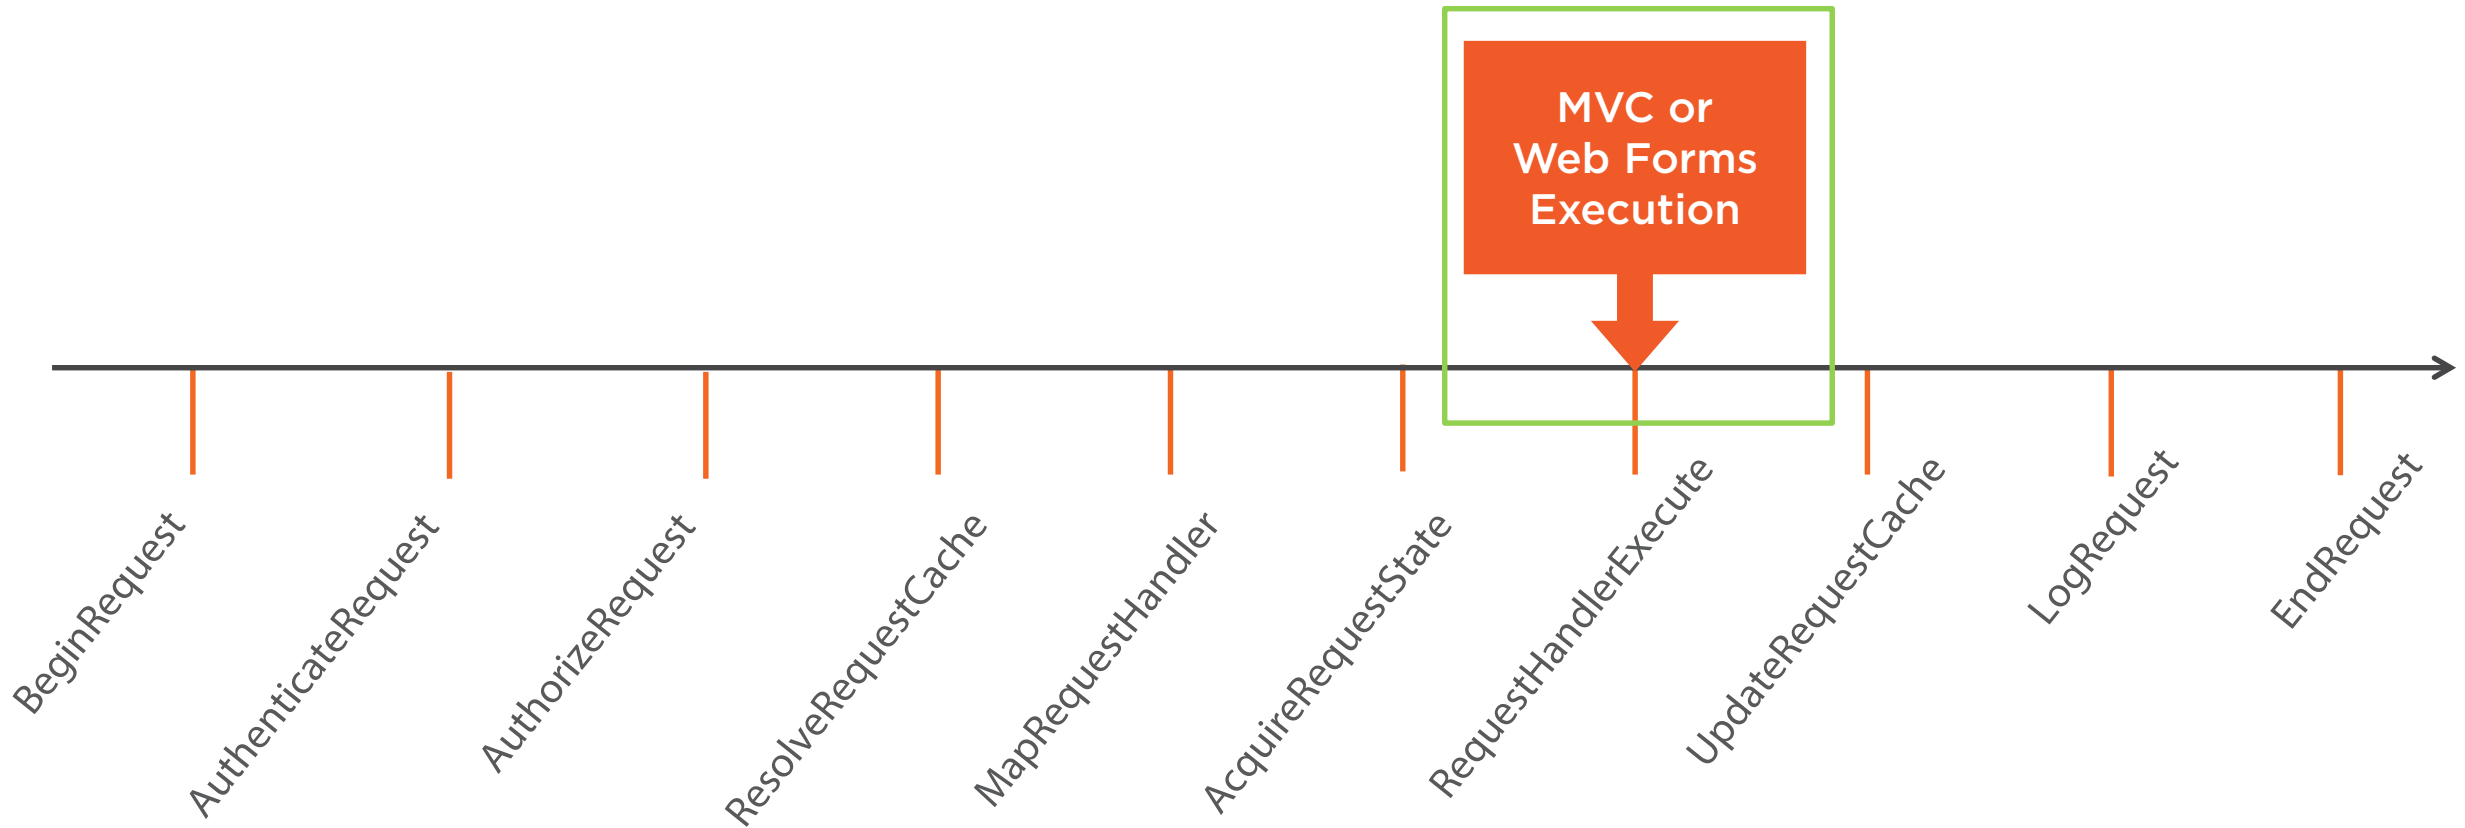

Selected and executed by ASP.NET to generate a response for a request

Handling Requests in Web Forms

HttpHandlers and the Application Life Cycle

* Event names shown represent both pre and post events

The Web Forms Page Life Cycle

A series of page processing events

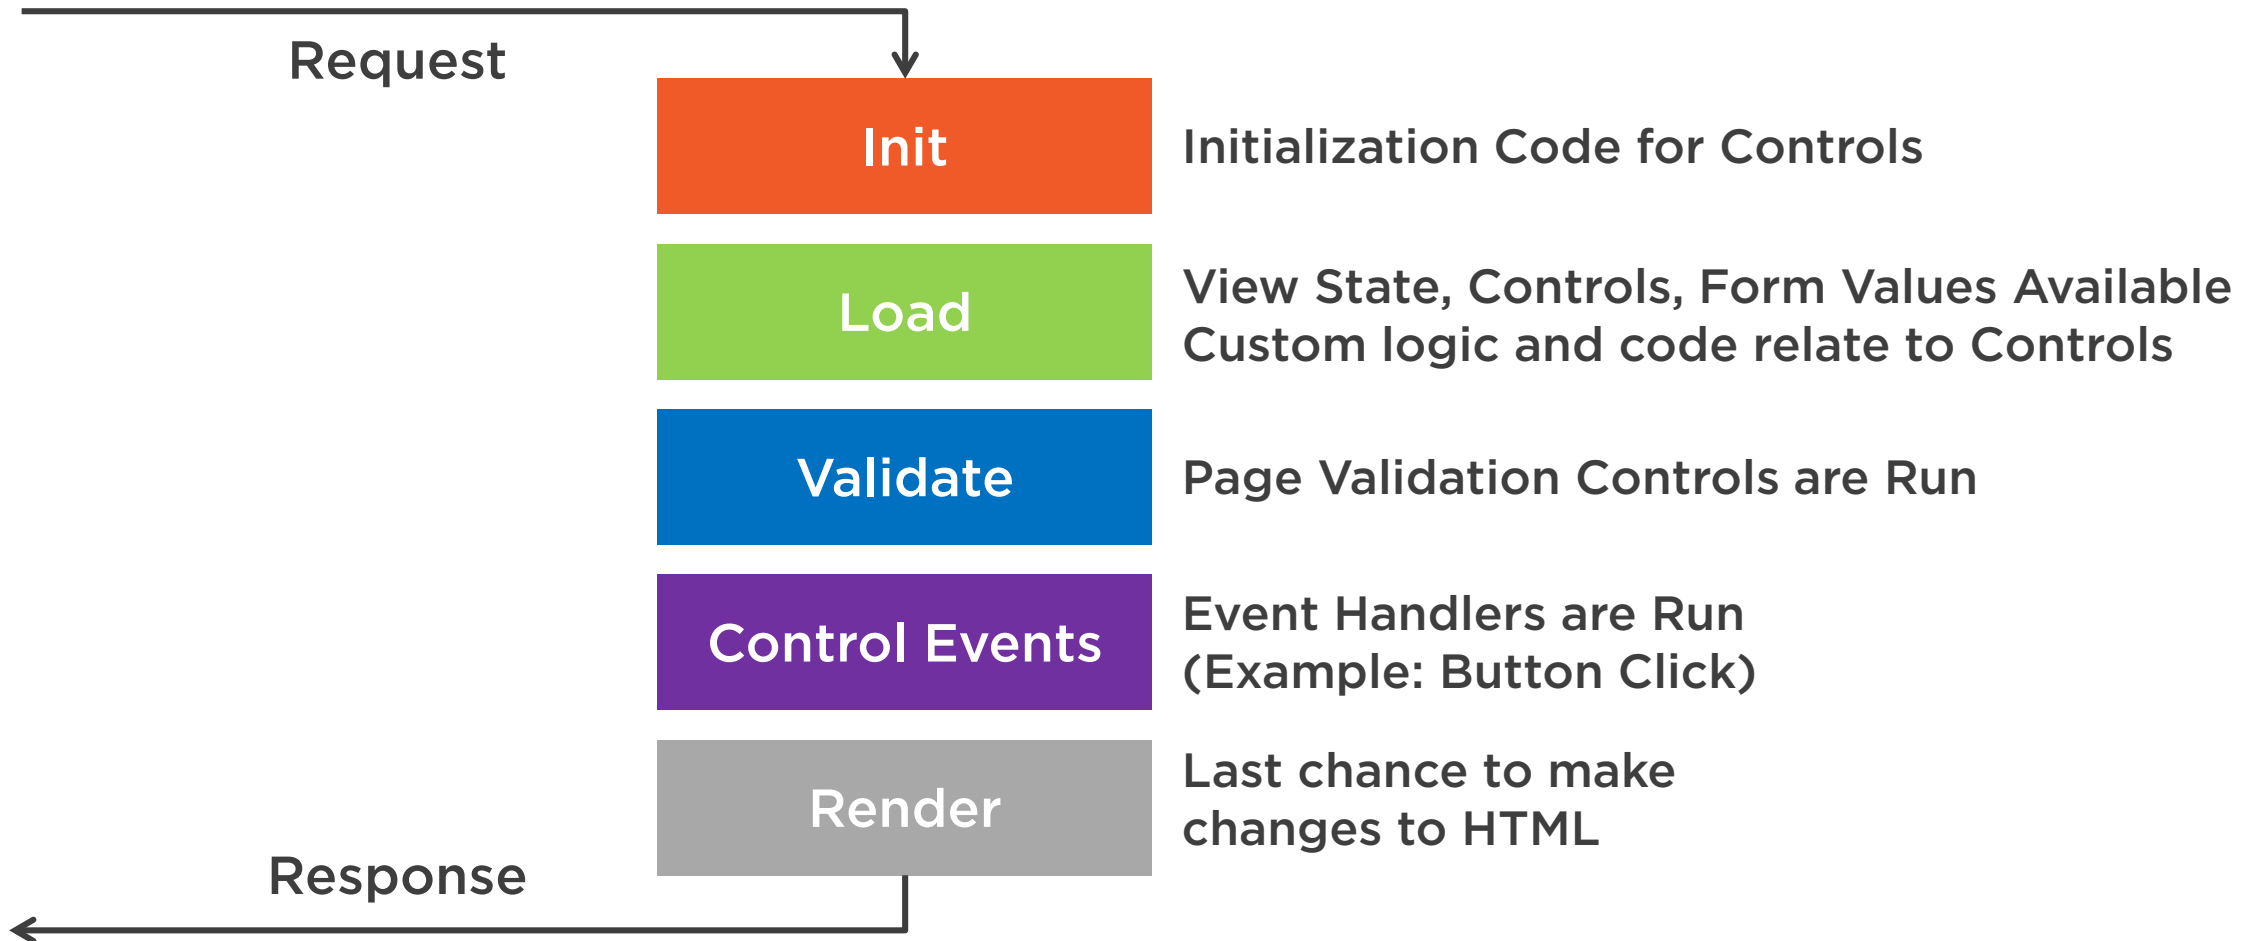

Abstraction over Http Requests

Ties together various features such as View State and Validation

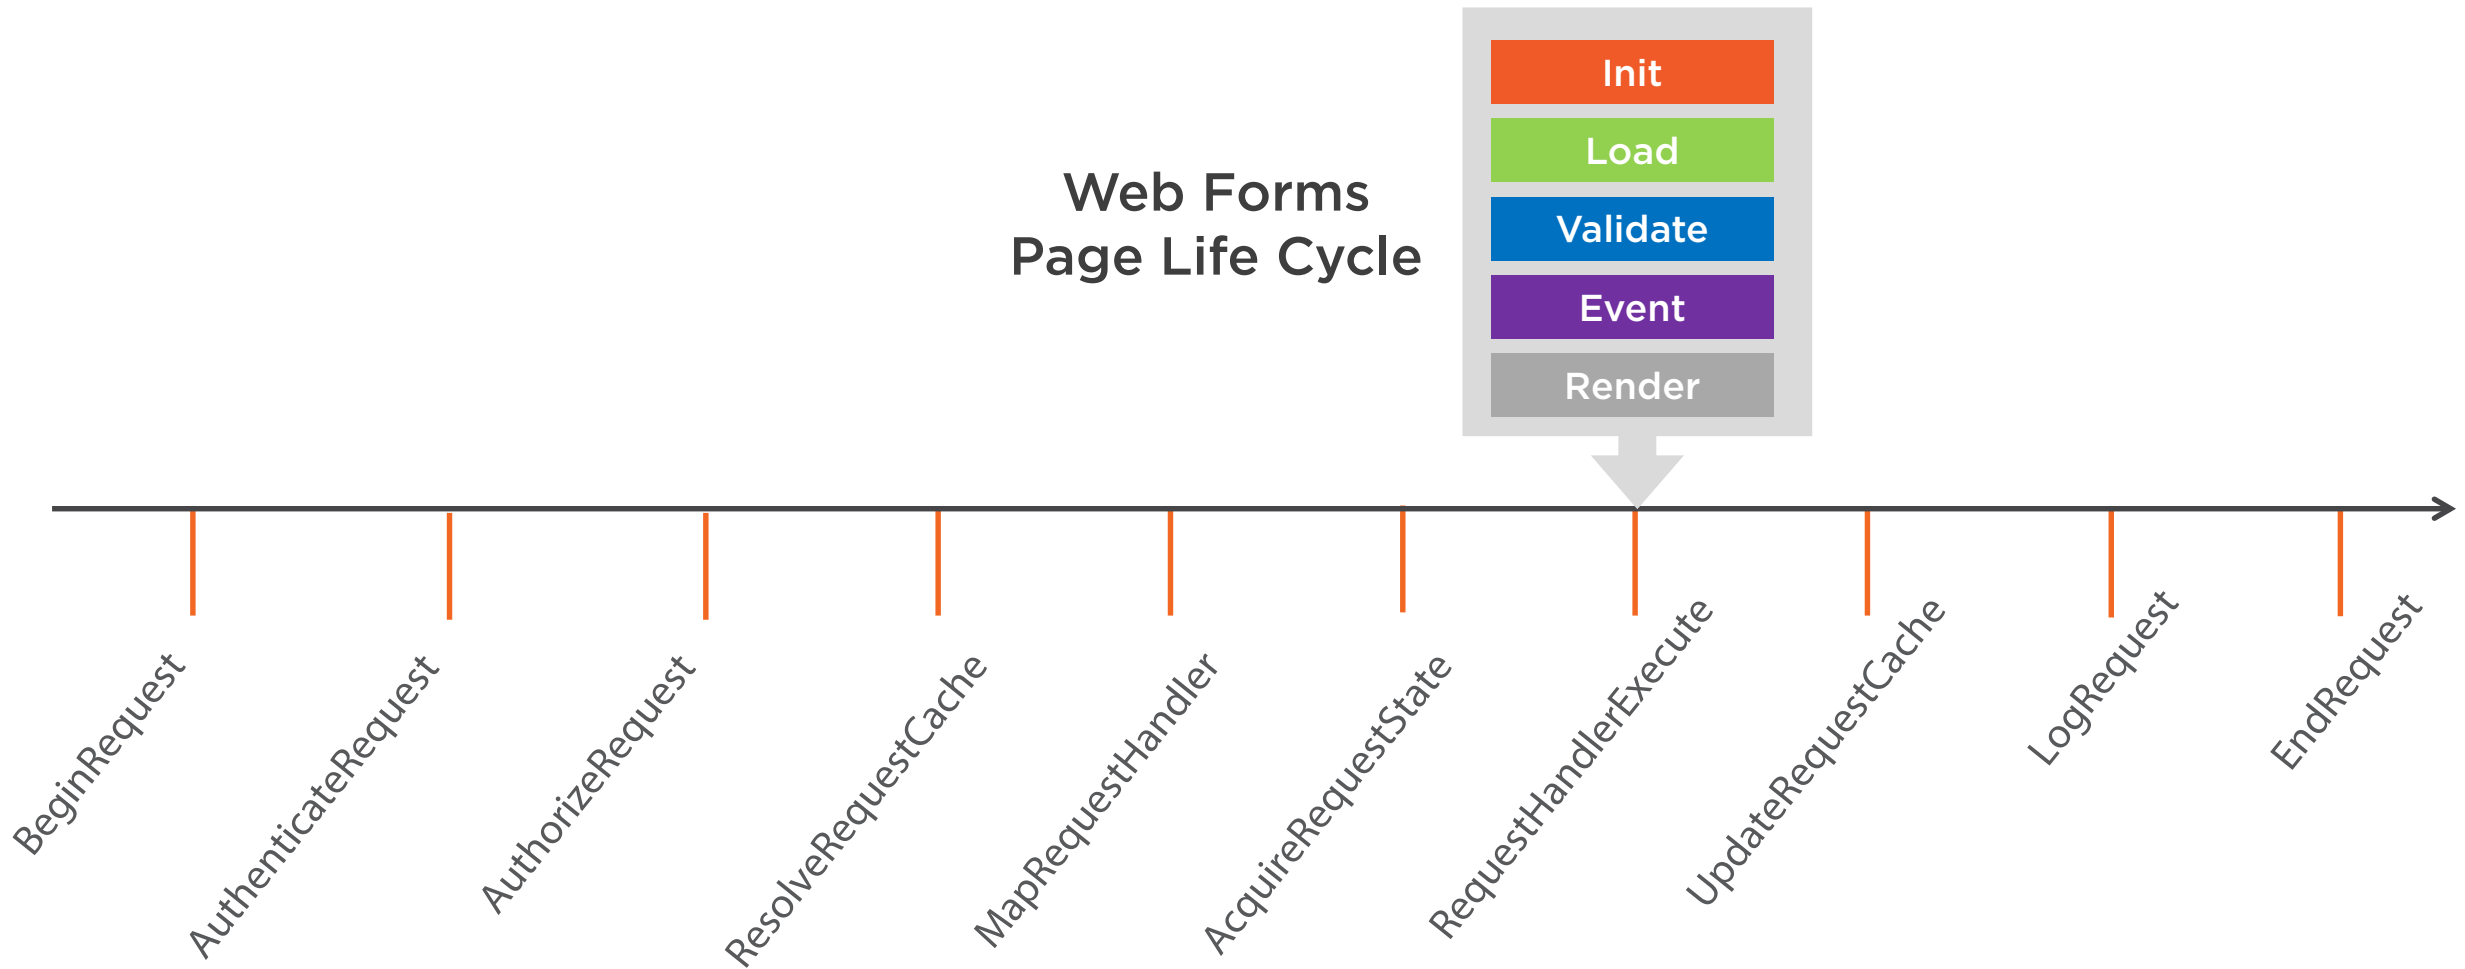

Many events, but only a handful used day to day

The (abridged) Web Forms Page Life Cycle

Web Forms and the Application Life Cycle

* Event names shown represent both pre and post events

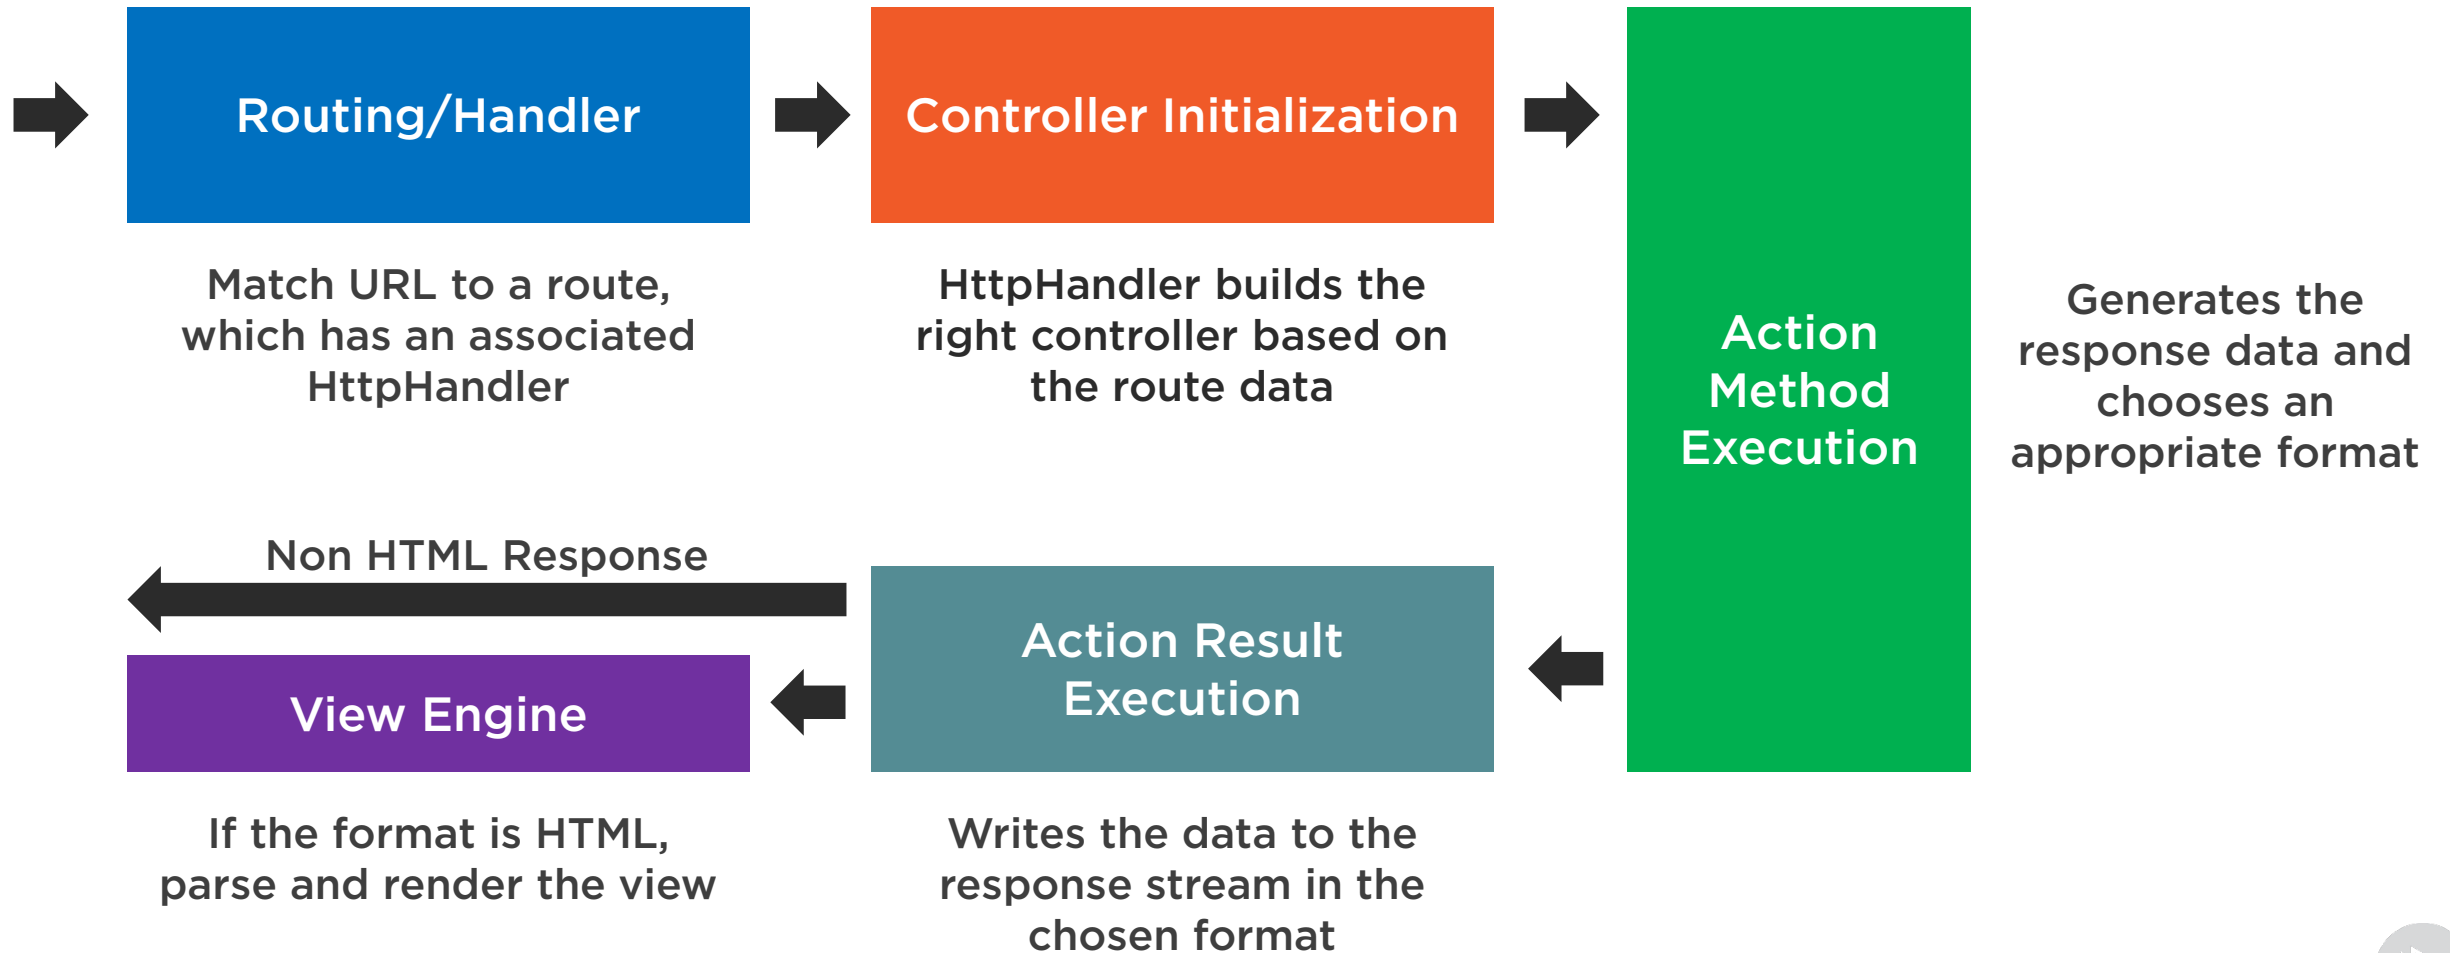

The (abridged) Web Forms Page Life Cycle

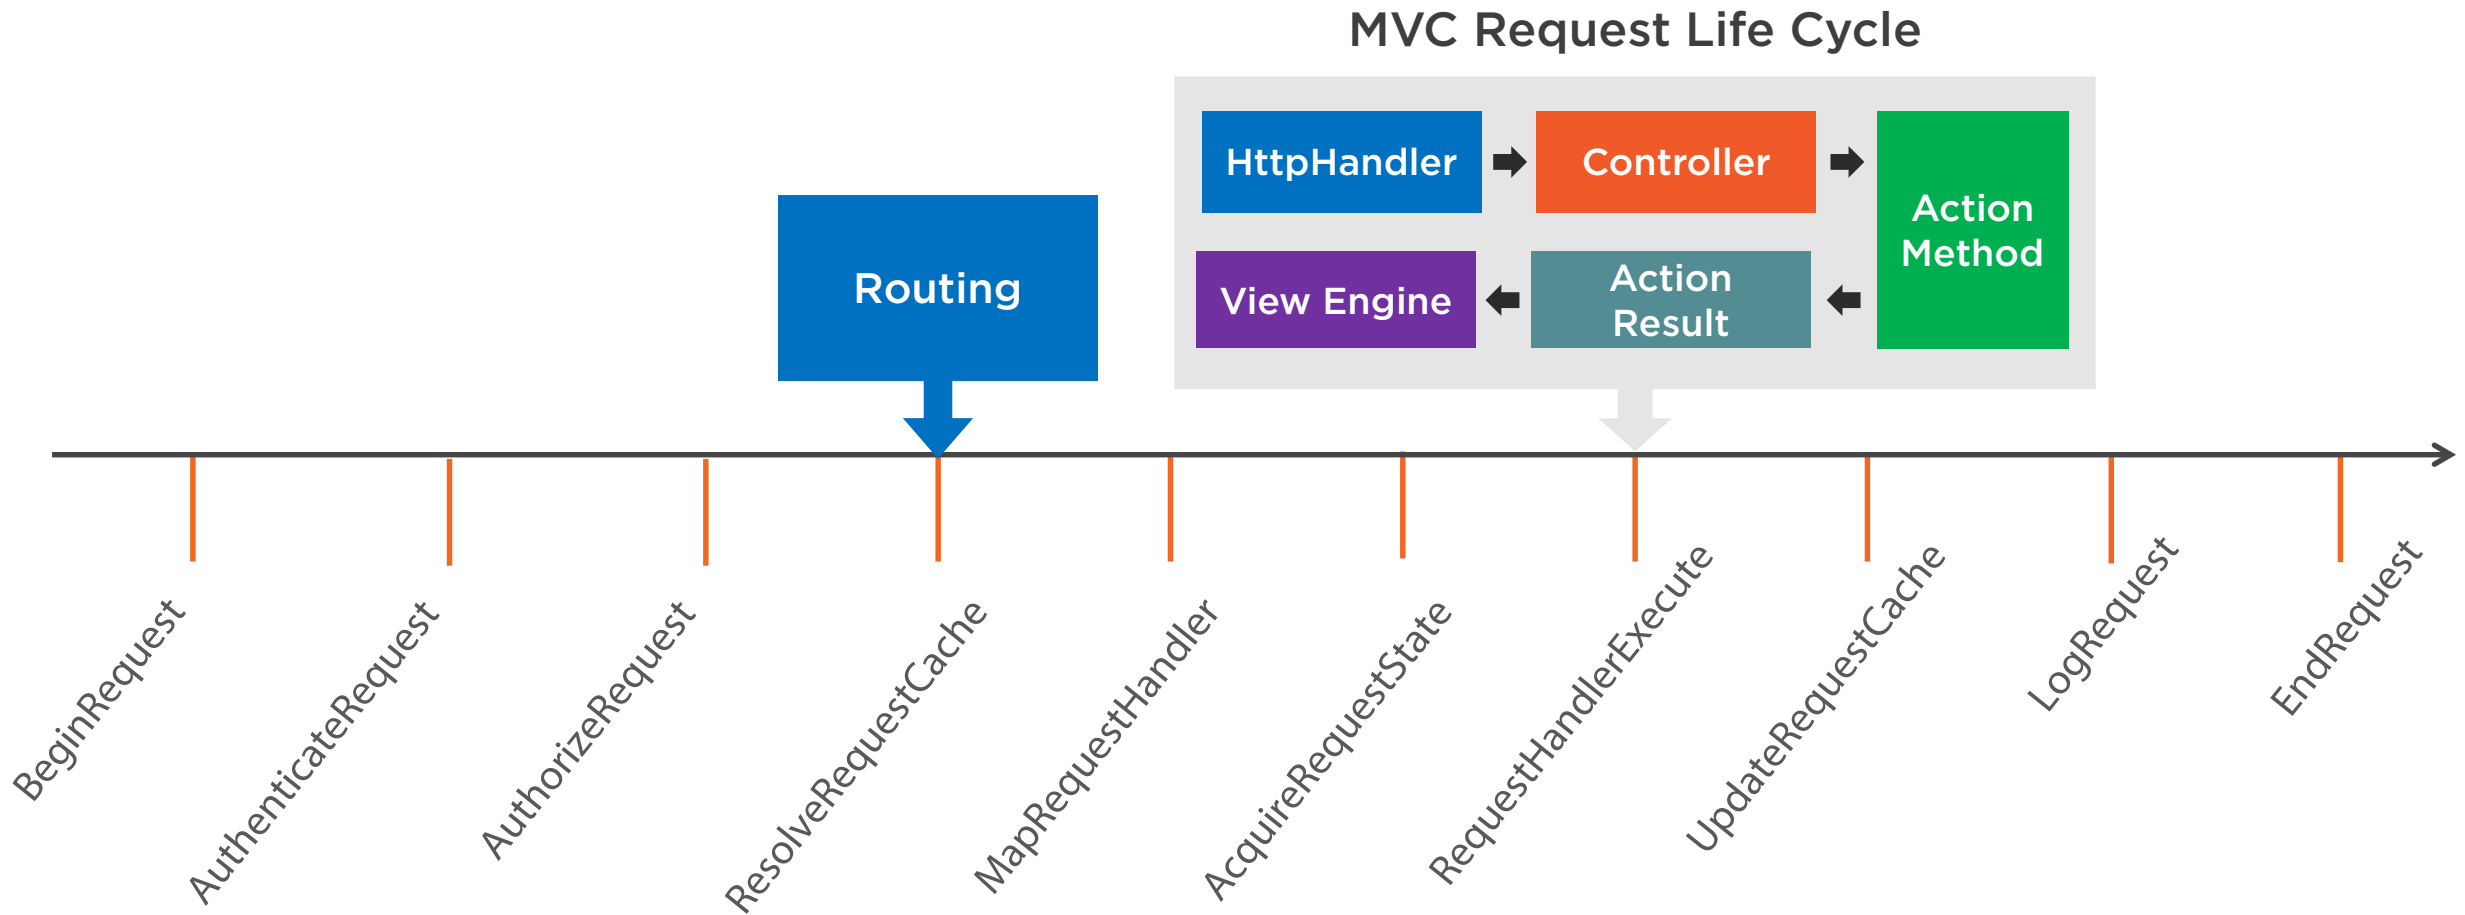

Handling Requests in MVC

The MVC Request Life Cycle

MVC and the Application Life Cycle

* Event names shown represent both pre and post events

```
public class MessagesController : IController{  
    public void Execute(){ }  
}  
  
public class MessagesController : Controller {  
    //Action Methods  
}
```

Implementing a Controller

Use the interface yourself, or just inherit!

Handling Requests with Controllers

MySite.com/Task/Delete

MySite.com/Task/Create

```
public class TaskController {  
  
    public ActionResult Delete()  
    {  
        return View();  
    }  
  
    public ActionResult Create()  
    {  
        return View();  
    }  
  
}
```

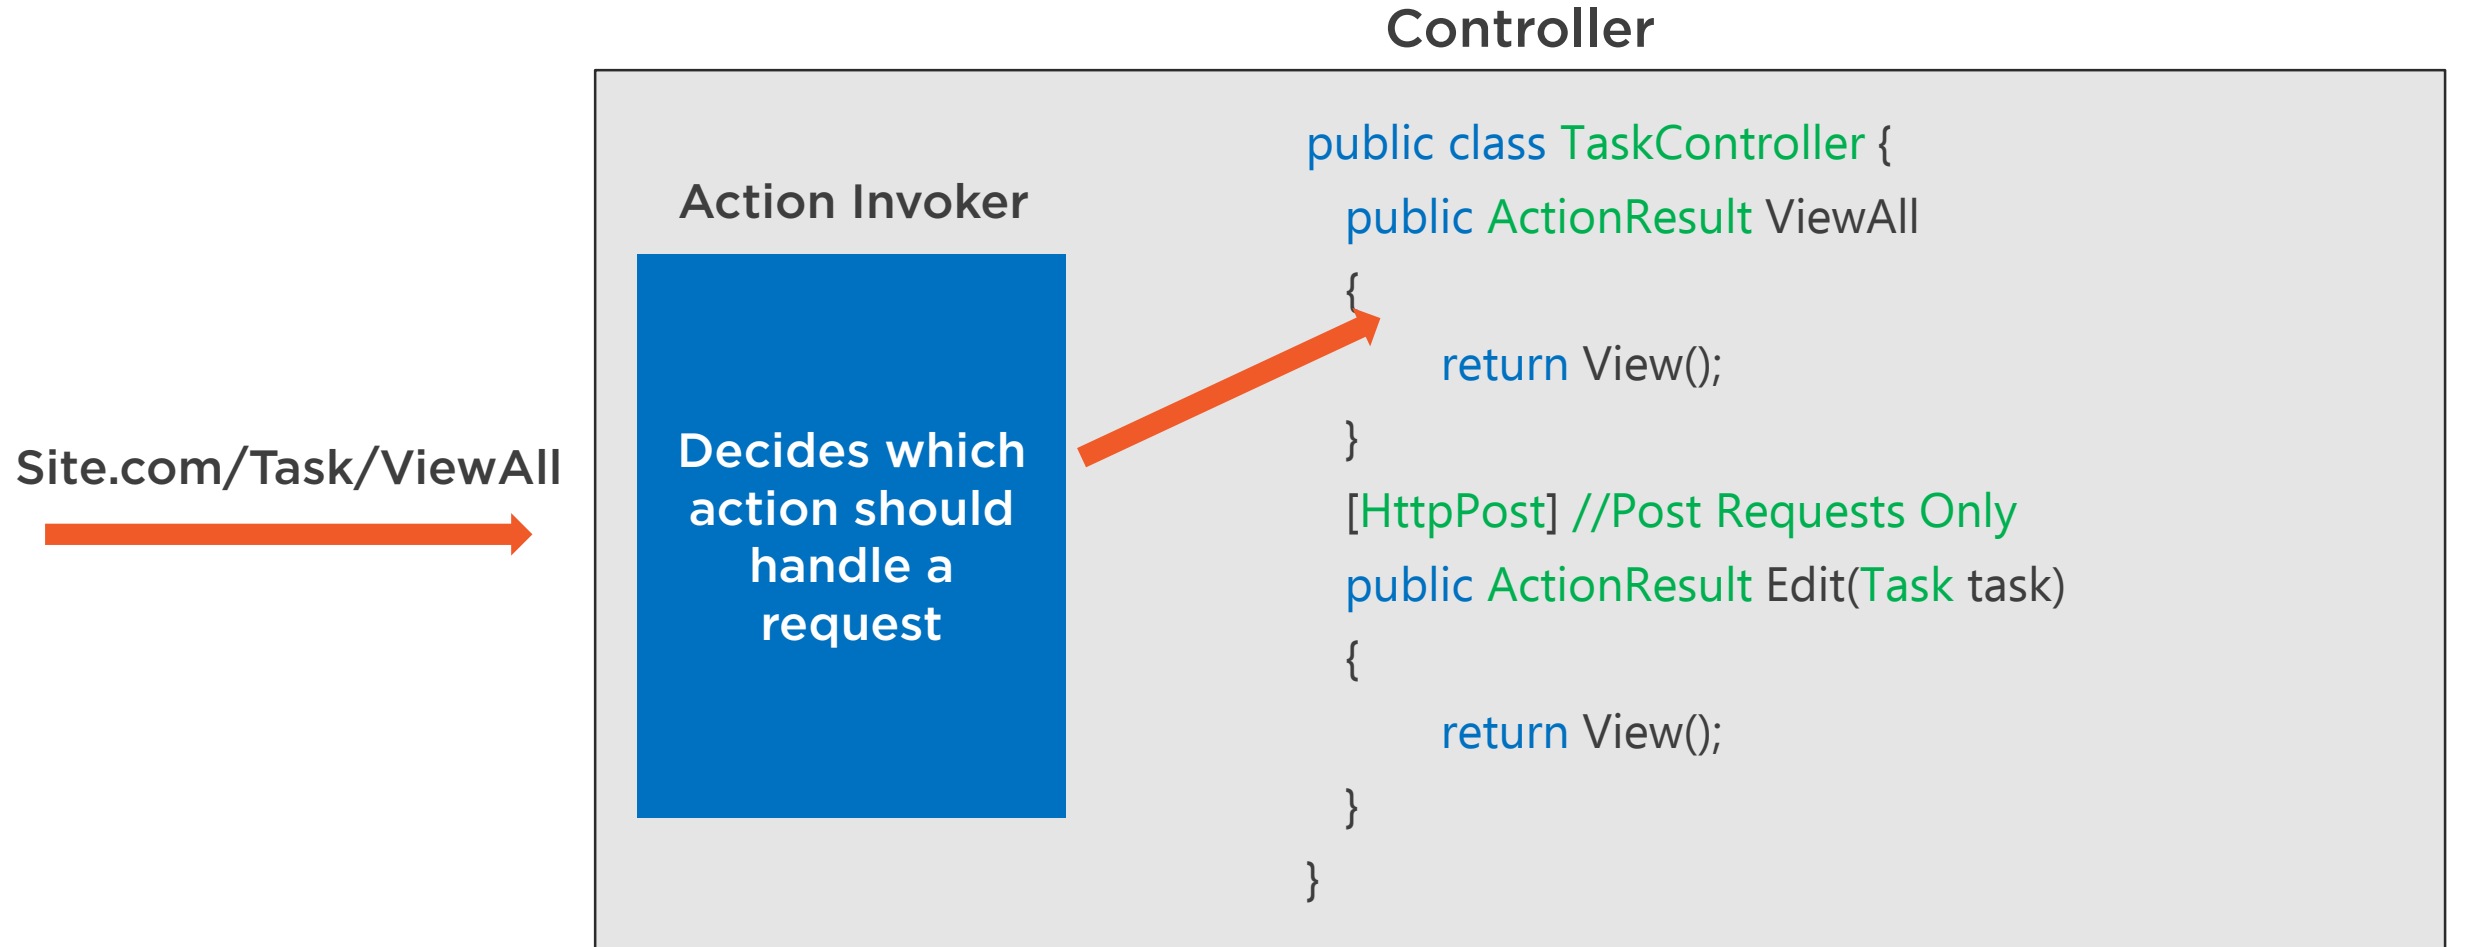

HomeController

MessagesController

WidgetController

Mapping Requests to Action Methods

Understanding ActionResult Types

ViewResult

Parses Razor Syntax
and returns HTML

JsonResult

Formats response as
JSON data

ContentResult

Writes out a string
result

ActionResult

What About Routing?

Routing Requests

Understanding Route and HttpHandler Selection

Request URL:

MySite.com/Tasks/Create/23

URLRoutingModule

Use the HttpHandler
associated with Route #3

I need a
matching route

Route #3
should work

- 1) api/{controller}/{action}/{id}
- 2) {controller}/{id}
- 3) {controller}/{action}/{id}

Too Many Segments

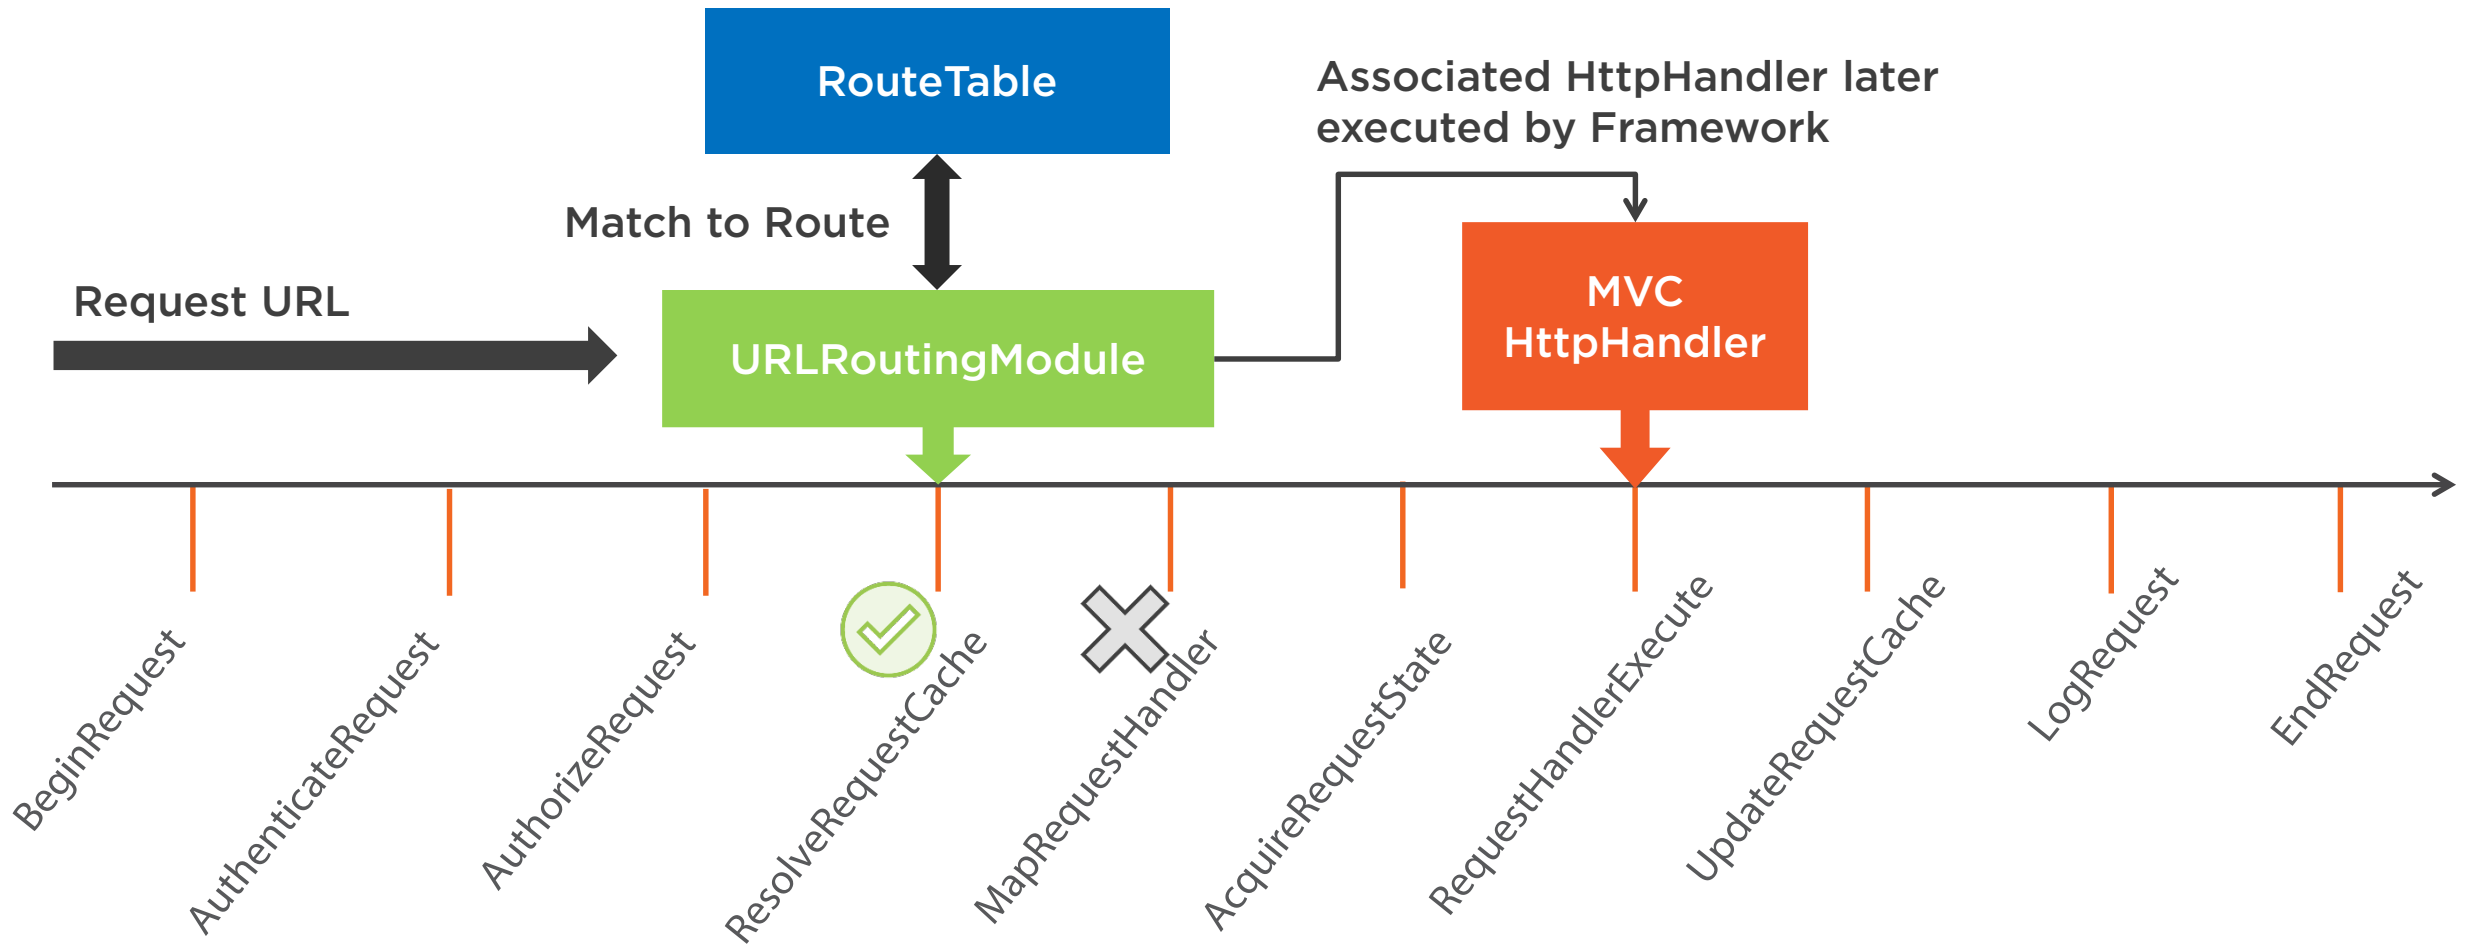

Too Few Segments

Matching Segments

Route Table

The URLRoutingModule at Work

* Event names shown represent both pre and post events

```
routes.MapRoute(  
    name: "Default",  
  
    url: "{controller}/{action}/{id}",  
  
    defaults: new {  
        controller = "Home",  
        action = "Index",  
        id = UrlParameter.Optional  
    }  
);
```

- ◀ Name of the route for easy referencing
- ◀ The URL segment pattern to match
- ◀ Default values can be provided as fall backs for missing segments
- ◀ Constraints that apply rules for whether a URL segment value is valid

Understanding Route Pattern Matching

URL: Mysite.com/Task/Edit/23

Matched Route: {controller}/{action}/{id}

The diagram illustrates the mapping between a URL and a code snippet. Three orange arrows originate from the URL 'Mysite.com/Task/Edit/23' and point to the placeholders in the route pattern '{controller}/{action}/{id}'. From these placeholders, three more orange arrows extend to the right, pointing to the corresponding parts of the code snippet: the first arrow points to 'TaskController', the second to 'Edit', and the third to 'id'. The code snippet is enclosed in a light gray box.

```
public class TaskController {  
    public ActionResult Edit(int id)  
    {  
        return View();  
    }  
}
```

The Route Ahead

Summary

Web Forms maps requests to physical pages in file directories

MVC dynamically handles requests by mapping them to action methods

Action Methods can return whatever data type and format is appropriate

MVC relies heavily on routing to process request information

ASP.NET provides considerable infrastructure for both frameworks
